# False GPWS warning and airframe damage, McDonnell Douglas MD-11, June 3, 2002

Micro-summary: This MD-11 experienced damage to the left elevator while executing a GPWS escape maneuver.

Event Date: 2002-06-03 at 1600 UTC

Investigative Body: National Transportation Safety Board (NTSB), USA

Investigative Body's Web Site: http://www.ntsb.gov/

# Cautions:

1. Accident reports can be and sometimes are revised. Be sure to consult the investigative agency for the latest version before basing anything significant on content (e.g., thesis, research, etc).

2. Readers are advised that each report is a glimpse of events at specific points in time. While broad themes permeate the causal events leading up to crashes, and we can learn from those, the specific regulatory and technological environments can and do change. Your company's flight operations manual is the final authority as to the safe operation of your aircraft!

3. Reports may or may not represent reality. Many many non-scientific factors go into an investigation, including the magnitude of the event, the experience of the investigator, the political climate, relationship with the regulatory authority, technological and recovery capabilities, etc. It is recommended that the reader review all reports analytically. Even a "bad" report can be a very useful launching point for learning.

4. Contact us before reproducing or redistributing a report from this anthology. Individual countries have very differing views on copyright! We can advise you on the steps to follow.

Narrative (Continued)		

#### METEOROLOGICAL INFORMATION

The weather at the Subic Bay International Airport at 1600 hours UTC was reported as wind variable at 3 knots, rain with broken skies at 1,800 feet AGL and overcast skies at 8,000 AGL, 4 miles visibility, temperature 75 degrees Fahrenheit, dew point 73 degrees Fahrenheit and altimeter 29.89 inches of Mercury.

## WRECKAGE INFORMATION

Post-flight inspection of the airplane revealed that the outboard portion of the left elevator, including the balance weight, was partially separated from the rest of the elevator. A 12 to 18 inch section of the elevator was missing. The right elevator appeared undamaged and underwent a detailed examination to confirm that it was undamaged.

## RESEARCH AND TESTING

According to Boeing, elevator damage to DC-10 and MD-11 airplanes can occur due to the dynamic response of the elevator when it is driven by the separated flow from the wing that results from a maneuver beyond the stall buffet boundary. During these events, the outboard elevators respond in their first torsion mode of about 10 cycles per second. The elevator horn balance weight contributes to this effect. The DC-10 and MD-11 elevators are equipped with an outboard damper to reduce the horn balance response, but this can be overcome by forces that occur when the stall buffet boundary is exceeded.

Analysis of the DFDR from this accident revealed that the airplane's design aerodynamic stall buffet boundary was exceeded during the abrupt GPWS pull-up maneuver.

The airplane was equipped with an upgraded Allied Signal enhanced GPWS and two upgraded Rockwell Collins LRA-700 radio altimeters. The enhanced GPWS receives inputs from two radio altimeters instead of just one, like the previous model, and is capable of sensing false radio altimeter tracking in airplanes like the MD-11, assuming that at least one of the radio altimeters is providing accurate data.

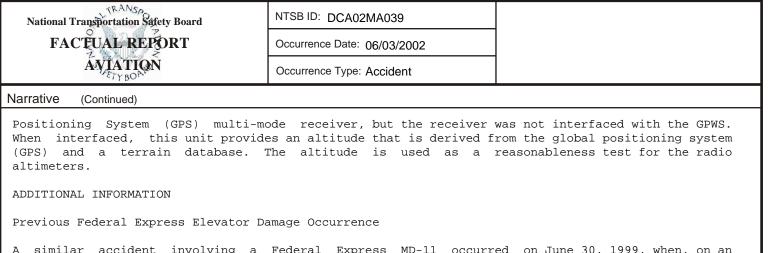

The radio altimeters, model LRA-700, P/N 622-4542-222, were tested by Rockwell Collins in Melbourne, Florida, on August 22, 2002. The no. 1 radio altimeter, S/N 4133, had no fault data logged. The no. 2 radio altimeter, S/N 4130, had faults logged from two previous legs. Both faults were internal faults listed as "lra-1 transceiver" and occurred prior to the incident flight. There were no faults listed for the incident flight. Both units passed the normal operation, return to service (with the exception of the 2500-foot sensitivity test), and temperature testing with no anomalies noted. The Melbourne facility lacked the support equipment to perform the 2500-foot altitude test so Rockwell Collins in Forth Worth, Texas, performed the remaining testing. Both units were tested and showed a sensitivity of 125 dB at the 2500-foot altitude. These measurements were within limits.

Both radio altimeters had been modified by Boeing service bulletin (SB), MD11-34-094. The SB modified the sensitivity of the LRA-700 altimeters in an attempt to reduce the frequency of false warnings during heavy precipitation. The modified altimeters were identified with a -222 part number, and their sensitivity was decreased by 6 dB per the SB.

The enhanced GPWS unit, P/N 965-0976-003-212-212, S/N 3930, was tested by AlliedSignal in Redmond, Washington. The GPWS unit passed the full Acceptance Test Plan with no anomalies noted. There was no examination of the antennae or the attaching hardware for the radio altimeter and the GPWS unit.

According to representatives of Federal Express, the airplane also had incorporated a Global

FACTUAL REPORT - AVIATION

A similar accident involving a Federal Express MD-11 occurred on June 30, 1999, when, on an approach to Acquino International Airport in the Philippines, the airplane experienced a GPWS "terrain-terrain" alert while descending through 9,500 feet in heavy precipitation. The pilot executed a GPWS escape maneuver, which resulted in similar damage to the elevators. The left outboard elevator and balance weight was completely separated from the rest of the elevator. The right elevator sustained substantially less damage. The airplane landed safely.

The airplane had a previous model GPWS unit that was capable of only accepting inputs from one radio altimeter. The airplane also had two previous model radio altimeters prior to a Boeing service bulletin that desensitized them.

According to Rockwell Collins, radio altimeters are susceptible to false warning due to reflectivity from ice crystals, heavy precipitation, or aircraft that fly underneath the airplane. The altimeters are designed to be sensitive and accurate enough for the auto-land mode, while minimizing false warnings.

History of DC-10 and MD-11 In-flight Elevator Damage.

According to information presented by Boeing in the 1999 GPWS incident and a previous NTSB investigation of a China Airlines MD-11 in-flight turbulence encounter in 1991 (NTSB/AAR-94/02), the damage found on this Federal Express airplane was similar to damage found on other MD-11s that experienced aerodynamic stall buffet.

In similar instances involving high-altitude upsets, damage to MD-11 elevators occurred with no reported loss of control. In the China Airlines incident report, the Safety Board concluded that the elevator buffet damage in that incident and previous incidents was caused by overstress but did not create an unsafe condition. In the 1999 GPWS incident, the captain stated that she had no indication after the escape maneuver that the elevators were damaged, and that the airplane's flight characteristics were "not irregular."

Integration of Global Positioning System with GPWS.

Prior to this accident, Boeing developed and released Service Bulletin MD11-34-116, allowing operators to install two GPS multi-mode receivers in place of the Instrument Landing System (ILS) receivers. Honeywell then developed Supplemental Type Certificate (STC) ST00536SE to allow the GPS information to be inputted into the GPWS computers to provide a reasonableness test for the altitude reported by the radio altimeters. The accident airplane had the GPS multi-mode receivers installed on February 8, 2002 but these receivers were not linked to the GPWS computer. As a result of this accident and other operational considerations at Federal Express, all MD-11s in the FedEx fleet have had the necessary equipment installed and the connections made to allow the GPS information to be used by the GPWS computer as of December 6, 2003.
